The Tel Aviv University Faculty of Medicine is Israel’s largest medical research and training complex. The Faculty of Medicine of Tel Aviv University (TAU) was founded in 1964. Research at the Faculty of Medicine is multidisciplinary, as scientists and clinicians combine efforts in basic and translational research. Research is conducted in the laboratories on the TAU campus by preclinical faculty members, and in the hospitals affiliated to the Faculty by PhD and MD clinical faculty members. The Faculty of Medicine includes the School of Medicine, the School of Health Professions, the School of Public Health, and the School of Dental Medicine. Education takes place in all these schools and in the Graduate School of Medicine, School of Continuing Medical Education, the New York State American Program and the B.Sc. Program in Medical and Life Sciences. This network of preclinical and clinical teams helps realize the ultimate goals of the research: the basic understanding of human pathophysiology and the prevention, diagnosis and treatment of disease. The research of PhD clinical faculty members are featured in this research brochure.

The Faculty of Medicine engages in joint teaching and research programs with nearly every faculty at TAU, including the Wise Faculty of Life Sciences, the Sagol School of Neuroscience, the Edmond J. Safra Bioinformatics Center, the TAU Center for Nanoscience and Nanotechnology, and multinational with schools, hospitals and research centers throughout the world. The faculty is known for research in the following areas: cancer biology, stem cells, diabetes, neurodegenerative diseases, infectious diseases and genetic diseases, including but not limited to Alzheimer’s disease, Parkinson’s disease and HIV/AIDS. Physicians and PhD researchers in 181 affiliated departments and institutes in 18 hospitals hold academic appointments at TAU. The Gitter-Smolarz Life Sciences and Medicine Library serves students and staff and is the center of a consortium of 15 hospital libraries.

The student body is made up of 750 Israeli students enrolled in the 6-year M.D. degree program, 300 American and Canadian students enrolled in a 4-year M.D. program chartered by the State of New York and accredited by the State of Israel, and a 4-year program for Israeli students for the M.D. degree, with 260 students. Approximately 200 students study dental medicine in a six-year program where they are awarded the D.M.D. degree and another 2,000 students are enrolled in the health professions programs where they will earn degrees in Communications Disorders, Nursing, Physical Therapy and Occupational Therapy. The Graduate School for Advanced Studies trains approximately 800 masters and doctoral level students in the biomedical disciplines, with a special emphasis on a multidisciplinary approach and application of fundamental knowledge to important biomedical problems.

The Faculty of Medicine is led by the Dean, Prof. Prof. Karen Avraham, Associate Deans Prof. Rina Rosin-Arbesfeld, Prof. Eli Sprecher, Prof. Neta Erez, Prof. Anat Gafter-Gvilli, Prof. Ronen Zaidel-Bar, Prof. Benjamin Dekel , and Assistant to the Dean, Michal Gilboa.

This brochure reflects the research being performed by the PhD Clinical faculty members at the Faculty of Medicine-affiliated hospitals.

Investigating Hormone Metabolism in Cancer

Positions
Associate Professor, Faculty of Medicine
Principle Investigator, Translational Oncology Laboratory, Sapir Medical Center, Kfar- Saba
Founder & CSO, DioTree LTD.

Research
Our research deals with the role of thyroid hormones (T4 and T3) in cancer progression and on the development of a novel class of targeted cancer therapy. A set of small molecules that specifically block the thyroid-cancer axis were developed. Our research group is the first to show the potent elimination of various cancer types by these novel drugs.

Publications

Tumor growth is promoted by (A) The thyroid-integrin membranal axis (B) The enzyme DIO3 which catabolizes intracellular thyroid hormones. DIO3 inhibitors lead to tumor regression.

Multiple Myeloma in its Bone Marrow Niche

Positions
Senior Lecturer, Faculty of Medicine

Research
We study multiple myeloma (MM) within its bone marrow (BM) microenvironment. Our group has uncovered intricate signals underlying the dynamic crosstalk between the MM and BM resident Mesenchymal Stem Cells (MSCs) that design the malignant cells’ phenotype and niche and drive the malignant process from pre-malignant states to treatment refractory disease. One such mechanism is manipulation of translation-initiation in niche BM-MSCs and MM cells by direct contact and secreted components such as extra cellular matrix and microvesicles. Another strategy is using the Cannabis compound CBD to modulate the dialogue.

Ongoing studies using cutting edge cellular/molecular and high throughput techniques has led to the identification of signals unique to the malignant dialogue that may be selectively targeted to improve MM treatment. Further discoveries have shown that MM-conditioned BM-MSCs disperse unique cargoes via microvesicles thereby promoting MM progression. Indeed, much of our interest is now focused at delineating the conversion of BM-MSCs into cancer supporting entities.

Throughout our studies we maintain tight collaboration with expert clinicians at the Meir Medical Center that gives us direct access to primary tissue samples and maintain relevance to state of the art treatments and clinical approaches. The research is expected to yield markers for disease progression and new therapeutic targets central to MM-BM niche collaboration, which is perceived as the major obstacle to MM cure.

Drug Delivery into the Brain, Brain Tumors and Brain MRI

Positions
Associate Professor, Faculty of Medicine, TAU
Chief Scientist, The Advanced Technology Center, Sheba Medical Center
Patent committee member, Sheba Medical Center

Research
The MR Research Group at the Advanced Technology Center of the Sheba Medical Center focuses on pre-clinical and clinical research, with an emphasis on brain, brain tumors, drug delivery and MRI. The hospital setup, enabling pre-clinical/clinical research, close access to physicians and patients, and close collaboration with the industry, forms an optimal environment for translational medical research, which is the nature of most of our research projects. One of the MRI methodologies, developed by the group for differentiating active tumor from treatment-induced effects in patients with brain tumors, has been licensed to an international company and is being used for clinical decision making in various hospitals around the world. Research performed in an attempt to extend this methodology to breast cancer and lung cancer is ongoing.

Publications

MRI-based treatment response assessment maps (TRAMs) for differentiating tumor from treatment effects in patients with brain tumors:

Immunotherapy of Brain Tumors: From Basic Mechanisms to Clinical Translation

Positions – Ilan Volovitz
Lab Head, Cancer Immunotherapy Lab, Neurosurgery Department, Tel Aviv Sourasky Medical Center, CSO Pyxis Diagnostics

Positions – Zvi Ram
Chairman, The Neurosurgery Section, Tel Aviv Sourasky Medical Center
Full Professor, Faculty of Medicine
Former Chairman, Tumor Section of European Association of Neurosurgical Societies

Research
Our laboratory studies the unique immunology of brain tumors by combining basic-science with clinically-applied investigation. Utilizing the discrepancy between the relatively weak immune surveillance inside the brain and the potent one outside it, the lab has developed a novel method to treat brain tumors utilizing a concept we termed ‘Split Immunity’. The concept was recently translated from rats to human glioblastoma (GBM) patients. To monitor the post-therapy changes in the anti-tumor immune response, the lab has developed a unique set of high resolution immune assays that follow the peripheral (outside the tumor) and the intratumoral immune response. The technology was recently translated into a company focused on identification of predictive biomarkers for cancer immunotherapy.

Main research interests
- Development of scientific and clinical insights into the concept of ’Split Immunity’ and how it affects the treated patients.
- Mapping of the entire adaptive and innate cellular immune milieu found inside human brain tumors using advanced multicolor (up to 12-color) flow cytometry.
- Using a cell-centered approach called "Immune Cytomics" to study the network of interactions formed between the different intra-tumoral immune cells and between immune and tumor cells.
- Evaluating how novel, non-immune-based, treatments for brain tumors affect the anti-tumoral immune responses.

Immunotherapy of Brain Tumors: From Basic Mechanisms to Clinical Translation

Left: Samples from patients with glioblastomas, low grade gliomas, metastasis from a peripheral tumor to the brain, and an epithelial lesion were flow cytometrically analyzed using the lymphocytes, innate and dendritic cell (DC) panel. Frequencies of each identified cell subset were calculated to all immune cells within the lesion (depicted as pie chart) and to the total number of immune cells within the lesion (represented by the relative size of the pie chart). Hypothesis: a white blood cell count of frequency Right: A Patient’s brain tumor sample was dissociated to single cells, and stained using the immune cells' panel. Following gating of cells identifiable by this panel, the cells were color-coded and overlaid in a multipanel display.

Deferasirox is a rationally-designed oral iron chelator used to reduce chronic iron overload in patients who receive long-term blood transfusions. We showed that this agent can induce apoptosis in mantle cell lymphoma.

Hematological Malignancies

Research

Our primary field of interest is finding new therapies or better therapies for the treatment of incurable hematological malignancies. Our projects focus on exploring the effect of new agents on different leukemia and lymphoma cell lines and patient samples. We study the molecular pathways involved in the initiation and maintenance of hematological tumorigenesis and try to understand the effect of the different agents on these molecular pathways. We apply cutting-edge technologies including, molecular protein and cellular biology, microarray and NGS analysis. Understanding normal hematological development and understanding the molecular effect of different chromosomal abnormalities (translocations, deletion, etc.) is essential for understanding the the processes leading to the induction and maintenance of hematological malignancies and for designing targeted treatments for these malignancies.

The Integrated Cancer Prevention Center (ICPC) has diverse and broad experience in translational research focused on early detection, prevention and therapy of cancer, particularly in tumors of the gastrointestinal (GI) tract. The team is highly experienced in clinical studies, molecular epidemiology as well as in molecular and cell biology studies of cancer. Currently, on-going research at the ICPC focuses on translational research, bridging between basic research in the laboratory and clinicians and patients in the clinical center. The center has a long history of planning, developing, and conducting clinical trials, with a main focus on investigator-initiated and cooperative group trials investigating the activity of drugs for the prevention and treatment of colorectal cancer (CRC). Dr. Shiran Shapira heads the laboratory, where basic research takes place. We devote our cancer research in the fields of early detection, prevention, and cancer therapy. The focus is on a wide range of biological areas covering cancer research, biochemistry, molecular biology, signal transduction, antibody engineering, protein expression and purification and gene delivery. The laboratory facilities occupy more than 300 square meters and is well equipped for research in biochemistry, molecular biology, tissue culture, cell biology etc.

**CD24 for early detection and surveillance of cancer using a universal simple blood test.** There are many attempts to develop a blood test for early detection, but none is in clinical use. CD24 is overexpressed in numerous human cancers. We have shown that a simple non-invasive blood test evaluating CD24 levels had good sensitivity and specificity for detecting colorectal adenomas and cancer, in patients undergoing screening colonoscopy in a tertiary medical center, independently on subject’s age, gender, size of adenoma and stage of CRC. Recently, we have significantly improved our technology, which based on measuring the levels of CD24, which could reliably identify individuals with different common types of cancer and may serve even as a novel predictive marker in cancer therapy and can identify family members that are at an increased risk for cancer. **HuCAMTech: The “Humanized” Chicken Embryo Chorioallantoic Membrane (CAM) as a personalized platform for screening drugs.** The proposed technology suggests an attractive and promising strategy for a rapid assessment of the efficacy of chemotherapy, hormone therapy, biological tools, immunotherapies, small molecules, cell therapy and other new drugs, as well as the measurement of the extent of sensitivity, responsiveness and inhibiting the proliferation of specific tumors, in one consistent model. Therefore, can significantly advance clinical behavior in cases of cancer. Currently there is no good prediction for response to therapy. Whereas rodents are the most widely used preclinical model for studying tumor development and metastasis, the chick embryo is a versatile 3R compliant model that is available as in or ex ovo, nutritionally self-sufficient, cost-efficient, reproducible and phylogenetically more similar to mammals than several other models of replacement. Its chorioallantoic membrane (CAM), a highly vascularized extraembryonic membrane that is located directly beneath the eggshell, provides the main advantage when considering models for 3D tumor formation and screening drugs in a personalized setting.

**Prevention.** Heading several international, multicenter trials in the prevention of GI tumors, and in particular sporadic and familial CRC. **Identifying high risk subjects through molecular epidemiology.** Our team has identified a new polymorphism in the APC gene (E1317Q), which is more common in Sephardic Jews and Arabs and is associated with a HR of ~4.

**Detection of new oncogenes that play a role in the multistep process of CRC carcinogenesis.** The research team at the Laboratory of Molecular Biology has been exploring, for several years, the hypothesis that CD24...
is a potential oncogene in GI malignancies and may serve as a biomarker and target for the treatment of cancer and cancer-related chronic inflammatory disorders such as, inflammatory bowel diseases (IBD).

The development of a novel Anti-CD24 antibody derivatives as a hope for the future. Antibody-based drugs are revolutionizing cancer, inflammatory and autoimmune therapy. Success depends on two important factors that are inseparable; lead molecule and promising target. CD24 and its antibodies meet these criteria. Targeting CD24 may be a promising treatment for various malignancies and for other applications as well. CD24 appears to be a promising target for many cancers that currently have limited treatment options. The uniqueness of the suggested antibody is its ability to recognize a specific and unique epitope in the matured core of the protein. The humanized mAbs (unarmed, bi-specific, toxin-conjugated, BiTE and other derivatives) against CD24 are very effective. The antibody was well characterized by means of PK, toxicity, stability, efficacy ( xenograft, PDXT and CAM-PDX) etc. Its mechanisms of action include ADCC, ADCP and TGI. The scFv derivative of the mAb was fused to lentiviral particles, in a specific therapeutic setting, and was given as a compensation therapy to five terminal ill patients.

Thinking “Outside of the box” using the Trojan Horse Strategy. This new therapeutic system aims to use exosomes, natural nanosized vesicles secreted by a variety of cells. The exosomes will be used as a delivery tool of specific cassette, carrying biological information, leading to the eradication of tumor cells. This cassette is based on the concept of utilizing specific hyperactive signaling pathway, which will activate lethal agents that will efficiently kill the tumor cells. It encodes a unique bacterial toxin-antitoxin system utilizes the frequency of mutations in certain oncogenes, such as Ras, leading to the transformation of normal cells into cancerous cells. In this way, the system will enable selective eradication of cancer cells without harming normal cells as previously validated in our published works. The protection of the healthy tissue is carried out by an active use of an antidote that specifically neutralizes the basal expression of the killing agent. By using the genetic status of tumor suppressor genes, such as P53, the expression of the neutralizing agent in the normal tissue increases. This treatment approach holds great promise for cancer treatment and will advance the management of human cancer due to the ability to modulate the vector depending on the genetic profile and type of cancer, and specifically overcome cellular resistance that is the major drawback of targeted therapy.

Wound healing. CD24 may represent a novel clinical intervention strategy to accelerate the healing of wounds both acute and chronic injuries for patients. The proposed treatment may enable faster recovery from injuries while reducing the risk of infection, toxicity and other possible side effects.

Malignant Cells-Derived Exosomes: Serving as Cancer Biomarkers

Positions
Senior Lecturer, Faculty of Medicine

Research
Exosomes are nanosized particles that are formed in different types of cells, travel in blood and other body fluids and carry a cargo of proteins and nucleic acids. This cargo is delivered to neighbouring cells. Our lab studies the role of exosomes in cell to cell communication and the potential use of exosomal cargo as biomarkers for diagnostics and followup of patients with cancer. Previously, we found that exosomes derived from various neoplastic cells contain hTERT transcript of telomerase, an enzyme that is unique to cancer cells and is only rarely found on non-neoplastic cells. Furthermore, this transcript is actively translated and mediates canonical and non-canonical functions in the recipient cells. In parallel we have found that in cancer patients, about 2/3 of the sera derived exosomes contain detectable telomerase transcript.

Subsequently we have shown that the transcript of telomerase in sera exosomes of patients with cancer including colon cancer and Lynch syndrome, brain tumors and lung cancers may serve as a diagnostic marker.

![Image of FITC-stained exosomes taken up by HUVEC cells analyzed by fluorescent microscopy.](image1)

![Image of FM-134 stained exosomes taken up by HUVEC cells analyzed by flow cytometry.](image2)

**Figure 1.** FITC-stained exosomes are taken up by HUVEC cells analyzed by fluorescent microscopy.

**Figure 2.** FM-134 stained exosomes are taken up by HUVEC cells analyzed by flow cytometry.

Subsequently we have shown that the transcript of telomerase in sera exosomes of patients with cancer including colon cancer and Lynch syndrome, brain tumors and lung cancers may serve as a diagnostic marker.

**Figure 1.** FITC-stained exosomes are taken up by HUVEC cells analyzed by fluorescent microscopy.

**Figure 2.** FM-134 stained exosomes are taken up by HUVEC cells analyzed by flow cytometry.
In addition to the transcript of hTERT we have recently studied the presence of alternative splice factors in cancer cells derived exosomes and found very promising results as to their presence in the tested ex-vivo samples. We plan to elaborate this study to numerous other hematological as well as solid tumor derived exosomes.

In other set of projects, we have shown that chronic lymphocytic leukemia (CLL) -derived exosomes recruit endothelial cells and monocytes to secrete cytokines which are then taken up by the neoplastic cells, providing them with a protection from apoptosis through STAT-3 activation. In contrast, these exosomes induce cellular death in normal B lymphocytes, their counterpart competing on the same biological niche.

In addition to the above we have studied the role of polycythemia vera (PV)- derived exosomes in conferring thrombotic presentation to these patients by acting as “mini platelets” spreading the JAK2 mutated oncogene into other body tissues.

Another new venue of the lab is the resistance of patients with acute myeloid leukemia (AML) to the treatment of the BCL-2 inhibitor, venetoclax. We hypothesize that at least part of venetoclax resistance is mediated via stroma cells derived exosomes residing in the bone marrow of patients with AML.

A prerequisite of the exosomal mediated crosstalk between cells is the ability of the recipient cells to engulf these exosomes. In Fig. 2, we show the vicious circle initiated by CLL cells to acquire survival advantage.

Developing Novel Adoptive Cell Therapies for Melanoma

**Position**
Senior Lecturer, Faculty of Medicine

**Research**
We perform cutting-edge translational research that can benefit melanoma patients, treated at the Sheba Medical Center. Our goal is to improve adoptive cell therapy (ACT) using human, autologous tumor-infiltrating lymphocytes (TILs), which is a well-established cell therapy for melanoma. While ACT was successful in treating melanoma prior to the era of immune checkpoint blockade (ICB), it is now frequently administered to patients who are refractory to ICB, and the success rates have dropped, indicating a development of resistance against ACT. Therefore, there is significant interest and an urgent need in the clinic to develop better TIL and T-cell products for patients with checkpoint inhibitor-refractory melanoma. We develop several technologies used to improve TIL anti-tumor capacities, using mRNA gene induction, CRISPR based gene deletion, metabolic reprogramming, establishing novel TCR therapies, and deciphering melanoma- TIL-microbiome interactons. We also work outside of melanoma, studying chimeric antigen receptor (CAR) T cell biology.

Elucidating the Molecular & Pathophysiological Mechanisms Leading to the Initiation and Progression of Cardiovascular Diseases

Research
We study the molecular networks leading to the initiation and progression of acute versus chronic presentation of various cardiac diseases. Currently we mainly focus on studying the following cardiac pathologies: 1. Acute myocardial infarction leading to left ventricular dysfunction; 2. cardiac volume overload- a prominent pathology in valvular diseases and chronic heart failure; 3. the prevalent presentation of cardio-renal syndrome. Utilizing the appropriate in vivo models as well as various molecular and cellular techniques, we have been trying to identify novel therapeutic targets for attenuating disease progression and to improve the clinical presentation of these devastating conditions.

Main ongoing research topics
The potential involvement of the cation channel TRPV2, which is highly abundant on peri-infarct immune cells, in the recovery processes following an acute myocardial infarction.
Elucidating the therapeutic potential of anti-metalloproteinase antibodies as well as reagents holding anti- histone deacetylase activity for the treatment of cardiac volume overload.
Cardiac mitochondria as a promising target for attenuation of cardiac dysfunction and progression to cardio-renal syndrome in patients with chronic kidney disease.

Stress and Inflammation in the Cardiovascular System

Positions
Senior Lecturer, Faculty of Medicine
Senior Researcher and Lab Head, Inflammation Research Lab, Department of Internal Medicine C”& E”, Tel Aviv Sourasky Medical Center

Research
• Cholinergic regulation of stress and inflammation.
• Urinary protein secretion as a risk for metabolic syndrome.
• Determination of new set of control limits for the disease marker.

The Tel Aviv Medical Center Inflammation Survey (TAMCIS) is a long-term, ongoing cardiovascular cohort study evaluating stress and inflammation in 22,000 apparently healthy working adults admitted to our medical center for routine annual medical check-ups. It is designed to evaluate the association between physiological and psychological measures of stress, inflammatory profile and their additive effect on cardiovascular risk.

Our database includes more than 50,000 visits with more than 600 parameters per visit; including medical history and medication, laboratory tests (Metabolic profile, Blood chemistry, blood count and Urine tests), ophthalmologist examination, exercise test and spirometry, psychological comprehensive questionnaire consisting of socio-demographic variables, personal and family medical history, health behaviors, among them dietary and sports habits, objective as well as subjective work conditions and various psychological scales such as depression, fear of terror, burnout, perceived control and social support. Research methods include basic molecular biology as well as sophisticated statistical models. The study team includes multidisciplinary researchers and physicians, from internal medicine, cardiology and neurology departments, and biostatisticians.

Innate Immunity of Digestive Tract and Liver Diseases

Positions
Senior Lecturer, Faculty of Medicine, Department of Clinical Microbiology and Immunology
Director, Research Center for Digestive Tract & Liver Diseases
Editorial boards: Immunometabolism (Hapres), Frontiers in Immunology
Committee member in “Aldema” – non-profit organization for advancing research on the treatment and prevention of digestive tract diseases

Research
Phagocytic type of innate immune cells, such as macrophages, monocytes and dendritic cells, play key tissue-specific homeostatic roles in organs of the digestive tract. Yet, they also fuel the pathological inflammatory sequence of digestive tract diseases, while preserving the potential to facilitate recovery. Our group strives to decipher the cell-specific immunoregulatory mechanisms that dictate the pathological versus restorative behavior of these innate immune cells in health and disease. We study the involvement of these cells in diseases of the digestive tract and metabolic syndrome, such as: liver fibrosis, metabolic dysfunction associated liver disease (MAFLD), obesity-induced type 2 diabetes, eosinophilic esophagitis, inflammatory bowel diseases (IBD), colorectal cancer, and hepatocellular carcinoma. We combine state-of-the-art in vivo transgenic mouse models with human patient samples and apply advanced immunological, genetic, molecular and imaging approaches. Our studies have greatly contributed to the field of gut and liver immunology with the functional definition of distinct macrophage subsets in these organs and their involvement in the respective diseases. We believe that mechanistic insights derived from our research would enable the design of more sophisticated cell-specific therapeutic approaches.

Among our main research topics:
• Unravelling key immunoregulatory molecules dictating the inflammatory versus restorative activity of macrophages in various diseases of the digestive tract. Our studies have illuminated COMMD10 as a pivotal immunoregulator in macrophages, regulating their differentiation, inflammatory and metabolic activities, and survival during diseases of the digestive tract.
• GIP receptor (GIPR)–GLP1 receptor (GLP1R) multi-agonists are at the front of treatment for type 2 diabetes and metabolic syndrome diseases. In the last decade, our lab has unraveled a key beneficial effect of these molecules on gut and liver immune regulatory mechanisms.

Studying innate immunity in digestive tract diseases. (A) Expression of GIP receptor (red) in perivascular adipose tissue macrophages in the visceral white adipose tissue. (B) Increased expression of the matrix metalloprotease ADAM8 (gold) in esophageal epithelial cells in mice subjected to EoE model. (C) Colocalization of liver resident macrophages – Kupffer cells (red) in their niche with hepatocytes (DAPI), hepatic stellate cells (yellow) and endothelial cells (cyan). (D) COMMD10 (green) localization in the cytoplasm, nucleus (DAPI) and mitochondria (red) of human macrophages.
immunometabolic roles for GIP during obesity, in supporting BM hematopoiesis and the restraining of adipose tissue macrophage inflammatory activity.

• We study the immunometabolic activities of the S100A8 and S100A9 alarmins in obesity and thermogenesis. Our lab has defined a deleterious role for S100A8/A9 in obesity and cold-induced adaptive thermogenesis, while S100A8 and S100A9 homodimers are beneficial.

• Eosinophilic esophagitis (EoE) is a rare, yet emerging, chronic type 2 immune-mediated disease, characterized by esophageal dysfuction. Utilizing a novel mouse model and our own EoE patient biobank, we study the association between EoE and an altered composition of the microbiome along the GI tract, as well as the cellular immune mechanisms that link between the microbiome and EoE development. We also study the role of S100A8 and S100A9 alarmins in the development and resolution of EoE.

Investigating the Mechanisms of Liver Steatosis, Obesity and Cholestatic Injury

Positions
Principal investigator, Research Center for Digestive Tract and Liver Diseases
Tel Aviv Sourasky Medical Center
Senior Lecturer, Faculty of Medicine

Research
Our lab is investigating two main diseases, liver steatosis in models of diet-induced obesity and insulin resistance and cholestatic liver injury. Obesity and the metabolic syndrome accompanying it affect a large percentage of Western world population and the obesity epidemic is only expected to increase, therefore it's of the utmost importance to understand the mechanisms involved.

Cholestatic liver injury can be caused by various factors that impair bile flow and result in accumulation of bile in the liver, such as genetic defects, structural/mechanical obstruction of bile ducts impairing bile flow (e.g., common bile duct stones), toxins, and dysregulated function of the immune system. The two main cholestatic disorders in adult human patients are primary biliary cholangitis and primary sclerosing cholangitis for which liver transplantation is the only treatment as the disease progresses to liver failure. Specifically, we are investigating the roles played by sortilin, a trafficking molecule and a co-receptor, in both obesity and cholestatic liver damage, since we have found that sortilin deficiency has a protective role in diet-induced obesity and in murine models of primary sclerosing cholangitis. We are using both isolated liver cells (hepatocytes, cholangiocytes) as well as the cre-flox model where sortilin is deleted in various liver cells in order to further elucidate the mechanisms and signals regulating the protective roles of sortilin.

Staining for cytokeration 19 (red) shows formation of epithelial bile duct cells after cholestatic injury induced by bile duct ligation in Sort1^-/- mice and induction of proliferation of bile duct cells by administration of leukemia inhibitory factor (LIF).

Research
Our lab is studying the processes involved in linear growth in children, in close collaboration with the Institute for Endocrinology and Diabetes at the Schneider Children Medical Center. The study aims to decipher novel regulatory mechanisms for enabling the development of better monitoring and treatment modalities which are much needed in this field. Previously it was believed that hormones such as growth hormone and Insulin like growth factor 1 (IGF-1) are the most critical factor, however, most children with short stature that visit our institute, present a normal hormonal profile; therefore we decided to focus our attention on studying the target organ, the epiphyseal growth plate (EGP). Our model is based on the well-known connection between nutrition and linear growth.

We were the first to show that leptin, the satiety hormone secreted from adipocytes, directly activates the growth plate. We have shown that leptin administration to food restricted animals compensated for the reduced amount of food, leading to almost normal growth. We have further showed that leptin binds directly to specific receptors in the EGP and activates its known signal transduction pathways including Stat3/Jnk/ERK and that it activates the regulatory pathway of Ihh/Pthrp. Recently we found that high levels of leptin, especially during puberty activates the aromatase enzyme, which converts testosterone to estrogen. As estrogen leads to growth inhibition, this activation leads to growth cessation and premature closure of the EGP, culminating in short stature. These findings were supported by a clinical observation made in our clinic, showing that obese children may sometimes end up with short stature compared to their peers.

Short children may sometimes be treated with growth hormone even in the presence of adequate amount of the hormone, if they are very short. In order to follow their response to treatment, a sensitive biomarker is required, apart from height measuring, as this gives indication only after 6 months or more. We are studying different biomarkers in several setups in order to identify the most sensitive and specific ones.

Animal studies are performed to study the effect of nutrition on growth. We are using a model of food restriction induced growth attenuation followed by re-feeding in order to cause catch up growth, which is robust than average growth. We were studying the changes in gene expression, identifying the role of the transcription factor HIF1alpha, several micro RNAs and HDACs. A transgenic model we developed in which Sirt1 (an HDAC of family III) was specifically knocked down in the EGP showed that the affected animals had significantly less efficient growth and less efficient response to nutritional manipulation. Surprisingly, a
marked effect was identified in bone mineralization and structure of the cortical and trabecular bone compartments.

Microbiome analysis at different nutritional states revealed that food restriction led to significant changes in gut microbiota, similar to the differences reported between fat and lean humans. Using several different diets, we noted that specific ingredients in the diet, even when calories and macromolecules are similar, significantly affect gut microbiota and growth. These finding enable us to suggest future improvements to the growth stimulating formula that was developed by the clinic.

Quantitative proteomics of rat livers fed ad libitum or food restricted shows that unrestricted feeding is stressful for proteostasis with implications on life span. Over 1800 common proteins were significantly quantified in livers of ad libitum, restriction- and re-fed rats, which summed up into 92% of the total protein mass of the cells. Compared to restriction, ad libitum cells contained significantly less mitochondrial catabolic enzymes and more cytosolic and ER HSP90 and HSP70 chaperones, which are hallmarks of heat- and chemically-stressed tissues. Following re-feeding, levels of HSPs nearly reached ad libitum levels. The quantitative and qualitative protein values indicated that the restriction regimen was a least stressful condition that used minimal amounts of HSP-chaperones to maintain optimal protein homeostasis and sustain optimal life span. In contrast, the elevated levels of HSP-chaperones in ad libitum tissues were characteristic of a chronic stress, which in the long term could lead to early aging and shorter life span.

We have been studying the molecular background of the Maturity Onset Diabetes of the Young (MODY) in Israeli patients, and identified several mutations that are more prevalent in our population. We are currently involved in a clinical study on autoantibodies to type 1 diabetes. Collaborating with a group from the USA that developed an ultrasensitive method to identify autoantibodies we will follow children from the general population to identify the timing of autoantibodies appearance. These results will be used to educate the families that are at risk and maybe in the future will enable us to offer treatment that may postpone the appearance of the overt diabetes.

Alpha Linolenic Acid (Essential Omega-3): Its Role in Pregnancy for Optimal Brain Development & Long-Term Prevention of Disease in Offspring

Positions
Associate Professor, CAMEA, Faculty of Medicine
Researcher at the Bert Strassburger Lipid Center, Sheba, Tel Hashomer

Research
We study the effect of maternal dietary fatty acids quality during pregnancy and lactation on the gene networks that are involved in lipogenesis and thermogenesis in the offspring. Obesity-associated chronic metabolic diseases such as Cardiovascular, Type 2 diabetes and Non-Alcoholic Steatohepatosis are purported to have an early in utero origin. The nutrigenetic impact of fatty acids quality in normocaloric diets and healthy mothers during development is almost unknown. We are exploring this question by studying the metabolic and genetic evolution of the offspring from birth to adult age in our animal nutritional model and in humans. We apply the latest methodologies including biochemistry, lipidomics, molecular biology, and microarray analysis to identify and functionally characterize genes that regulate the lipogenic and thermogenic processes that determine the energetic balance leading to obesity or its absence. Understanding the normal or obesity prone gene programming during development and characterizing the associated fingerprint in the offspring at birth is essential for the early diagnosis and design of treatments to prevent long-term metabolic obesity-associated disorders that are leading causes of disease in almost 40% of world population and death.

Docosahexaenoic acid (DHA) is an omega-3 fat that can be made in the body from a precursor alpha

Protein interaction between products of genes upregulated (red full) or down-regulated (blue full) by ω3 essential fatty acid (ALA) or saturated fatty acids (SFA). Enriched functions are marked using open colored circles.
linolenic acid (ALA) or consumed directly from fish. DHA is essential for normal brain function and its levels increase dramatically during brain development. Much of the world consumes diets lacking DHA and relies on synthesis from a dietary precursor. Under normal conditions, in adults, the synthesis of DHA from its precursor appears to be enough to supply the brain. It is even possible that the synthesis of DHA from its precursor is enough to supply the infant brain during its growth. However, it has now become apparent that certain dietary factors, stress and genetics can influence the body’s ability to synthesize DHA, which could have long-term consequences on brain function. We have developed methods to study the synthesis of DHA from ALA in detail and we use mice to examine how different diets, stress and genetic factors influence the synthesis of DHA, brain DHA levels and brain function while the brain is developing. We are also examining human mothers in their fatty acid profiles compared to non-pregnant women, to establish a scientific basis for personalized needs of fatty acids during pregnancy for the wellbeing of both mother and child. We are contemplating the impact of maternal dietary ALA on the offspring’s epigenetic impact.

Epitranscriptomics: Gene Expression Regulation Through RNA Modifications

Positions
Deputy Director, Cancer Research Center, Chaim Sheba Medical Center
Senior Lecturer, Faculty of Medicine, Tel Aviv University

Research
Epigenetic modifications regulate gene expression to determine cell fate and responses to environmental stimuli. The mechanisms that orchestrate the dynamic and reversible deposition of these DNA and histone modifications have been studied extensively, and it is known that they participate in the core regulation of gene expression. By contrast, the role of epitranscriptomic (RNA) modifications in the regulation of gene expression is only starting to be revealed.

RNA modifications were previously known to occur in highly abundant RNA species, such as ribosomal RNA and transfer RNA. However, in recent years, thanks to studies by us and others, a growing number of modifications have been identified and characterized in low-abundance species of RNA such as mRNA and long non-coding RNA. These modifications regulate RNA processing events such as splicing, transport, translation and turnover.

The epitranscriptome, as these modifications are now collectively known, comprises a growing number of chemical adducts, such as N6-methyladenosine, N1-methyladenosine, inosine, 5-methylcytidine, 5-hydroxymethylcytidine, pseudouridine, N6,2′-O-dimethyladenosine, N1-acetylcytidium, N7-methylguanosine, 8-oxoguanosine and 2′-O-methy. These modifications embed RNA transcripts with information additional to that carried in their sequence of bases. The discovery of dedicated cellular machineries that deposit, remove and recognize RNA modifications (known as writers, erasers and readers, respectively) has helped to reveal the essential roles of these modifications in cellular, developmental and disease processes.

Our group studies the effects of RNA modifications on gene expression by understanding the mechanisms responsible for their cellular decoding and the biological consequences in both normal physiology and disease. For example, modifications can change the charge of RNA bases and alter their base pairing properties, resulting in differential RNA folding. They can also form recognition elements embedded in the transcript’s sequence that modulate protein–RNA interactions. For this purpose, we develop novel technologies to detect and sequence modifications and look for new components of the cellular machineries responsible for the metabolism of modifications in particular and mRNA more broadly.

Extracellular Vesicles (EVs): A Biomarker and Therapeutic Tool

Positions
Senior Lecturer, Faculty of Medicine
Director, Hematology Research Laboratory for Extracellular Vesicles, Tel-Aviv Sourasky Medical Center

Research
Extracellular vesicles (EVs) are sub-micron membrane vesicles that shed from cells under various conditions. They found in body fluids of healthy individuals and their levels increase in a variety of diseases. EVs are divided according to size, synthesis route, and cell origin. EVs bear antigens reflecting their cellular origins, cytokines, fragments of DNA/RNA and miRNA that can be transfer to recipient cells, therefore play significant role in intercellular communication.

Over the past 18 years, our laboratory has made significant contributions to exploring the role of EVs in pregnancy complications, cancer (hematological malignancies: myeloma, AML, ALL and solid tumors such as breast cancer, colon cancer), in congenital disorders such as thalassemia and in trauma patients and patients with dementia. Additionally, the effects of EVs that shed from cell culture upon stimulation on other cells functions (such as endothelial, placental cells, airway epithelial, liver, pancreatic and ovary and breast cancer cell lines) were explored. We also focused on the therapeutic side of EVs and significant progress was made in our study on EVs derived from CAR-T cells as a potential therapy for cancer. During this period, my team and I published above 40 publications describing our research work.

Investigating the Molecular Basis of Pulmonary Fibrosis

Positions
Lecturer, Faculty of Medicine
Principle Investigator, Pulmonary Disease Research Laboratory, Meir Medical Center, Kfar Saba

Research
We study the effects of the microenvironment on fibrotic disease progression. In our lab, we culture primary human lung fibroblasts derived from normal and IPF tissues to explore molecular markers and mechanisms involved in fibroblast to myofibroblast differentiation. Using an idiopathic pulmonary fibrosis (IPF) conditioned matrix (CM) model that we developed, we investigate fibroblast-extracellular (ECM) interactions. We found that culturing normal fibroblasts on the IPF-CM leads to their differentiation towards myofibroblasts. This platform also enables the study of new drug candidates for fibrosis.

Publications

Normal human lung fibroblasts cultured on control (N CM) and IPF CM. As shown on the right side, the normal cells become elongated (2h), migrate and finally cluster into large aggregates (24h) following their culture on the IPF-CM.

Research
Rheumatic diseases are prevalent diseases that include variety of disorders, the most common among them are: Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA), Ankylosing Spondylitis (AS) and Osteoarthritis (OA). Those diseases are characterized by pain, swelling and synovitis of the joints. Nowadays new classes of medications have greatly improved rheumatic disease outcomes. However, biomarkers that will assist in the best therapeutic choice are lacking. Although, precision medicine is already in use in medicine fields, such as oncology, this field in rheumatology is lagging behind.

Our main research:

• Characterization of biomarkers for response to anti-rheumatic drugs – Generation of an assay to analyze patient’s immune cells response to drugs using ex-vivo conditions. Diverse immune cell phenotype alterations in response to each drug are being characterized. Our aim is that such assays will assist in drug choices for the individual patient and will optimize rheumatic diseases patient’s outcomes.

• Characterization of biomarkers to distinguish between different types of rheumatic diseases - The rheumatic diseases share common clinical presentation but also present differences in pathogenesis and radiographic findings. Those differences are translated into variances in the specificity and efficacy of therapies. Moreover, PsA disease diagnosis is based only on clinical
evaluation since diagnostic biomarkers are not available yet. Finding of new biomarkers may improve accuracy in the diagnosis of different diseases and may assist in therapy selection. The diagnosis may be helped by synovial fluid analysis. We aim to characterize synovial biomarkers that could differentiate between the different disease types.

Our laboratory is located in close proximity to the Rheumatology Clinic, allowing daily collaboration with the department and accessibility to human patient samples. We use advanced immunological and molecular approaches.

The scheme illustrates the lab main research fields: A. Development of ex-vivo assay to predict response to anti-rheumatic drugs based on immune phenotyping of patient immune cells. B. Identification of synovial biomarkers that will assist at diagnosis of different arthritis types.

Improving Management of Inflammatory/Autoimmune & Rheumatic Diseases Using Extracellular Vesicles and Medical Cannabinoids

**Positions**

Head of Research Laboratory, Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center (affiliated to Tel Aviv University).

**Research**

Our focus and goals at the lab are to establish innovative solutions and better ways to improve the current treatment for inflammatory/autoimmune and rheumatic diseases using the following research strategies:

1. Improved drug delivery using specific tissue-homing small extracellular vesicles ('exosomes')

   The specific synovial-homing receptor αvβ3 integrin is expressed on serum-derived exosomes (CD9+/CD81+) from rheumatoid arthritis (RA) mice. A. Total exosomes were isolated from pool of serum samples of RA mice (Collagen-induced arthritis model) (n=5) and Sham (n=5) mice. Exosomes homogenates were separated using SDS-PAGE and subjected to immunoblotting with antibodies against CD9, CD81, αv, β3 (Santa Cruz Biotechnology) and β-actin (R&D system). Total 7 µg protein were loaded into each well. B. Transmission Electron Microscopy (TEM) analysis shows a nano-size vesicle (~40nm) of exosomes derived from sera of RA mice.
to the diseased subjects and will naturally find their way to the inflamed tissue. We believe that this approach will increase the specificity and efficiency of the current treatment, therefore it will reduce side effects as compared to the delivery of free drugs and will improve the quality of life of patients with inflammatory/autoimmune/rheumatic diseases.

2. Exploring the effect of novel therapeutic candidates: anti-inflammatory small molecules and/or natural compounds (such as plant-derived cannabinoids) in experimental inflammatory/autoimmune diseases (Animal models of Collagen-induced arthritis, DSS-induced colitis, Bleomycin-induced systemic sclerosis etc.). Moreover, our lab exploring the effect of these therapeutic candidates on inflammatory mediators - in vitro (using relevant primary cells and/or cell lines) and ex vivo, in patients-derived blood components (such as PBMCs) and/or in their relevant inflamed tissue biopsies.

3. Our lab has expertise also in the field of autoantibodies, through the measurement of patient-derived panel of autoantibodies, isolation of autoantibodies (total IgG/IgM or specific IgGs) from blood samples of patients and through exploring their potential pathogenic role using passive transfer of these antibodies into naïve animals following evaluation of clinical manifestations (reported by the patients) in the animals.

4. We are focusing also in exploring the potential immune-related pathomechanism of fibromyalgia syndrome – through examination of the effect of various conventional and unconventional treatments (Neurofeedback, cannabinoids etc.) on patient-derived immune system components and neuroinflammatory mediators.

5. Our lab is also focusing on the effect of dangerous adjuvants (such as silicone, metal implants etc.) on human health in general and more specifically on the immune system.

**Research**
CAR (Chimeric Antigen Receptor) T cell therapy, developed by the award-winning researcher Professor Zelig Eshhar (the previous head of our lab), genetically engineers and trains T cells to specifically recognize and kill cancer cells. We recently developed a dual specific CAR for multiple myeloma, in which the activation and the co-stimulation domains are separately provided by two CARs. This split configuration allows for full and efficient stimulation of the T cells only upon engagement with tumor cells expressing both antigens and sparing cells with single antigen presentation, thus overcoming the “off tumor on target” toxicity. Furthermore, we are developing several combined therapies to overcome today’s challenge of treating solid tumors as for their suppressive tumor microenvironment. Another aspect our lab is developing a better CAR T manufacturing platform.

The Coagulation Cascade: Hemostasis and Cellular Aspects

Position
Associate Professor, Faculty of Medicine
Head, TAU Amalia Biron Research Institute of Thrombosis and Hemostasis

Research
Our research focuses upon the coagulation cascade and addresses two main topics:

Basic, clinical and translational evaluation of hemostasis among patients with bleeding disorders in order to define personalized treatment. There is no ultimate lab assay available in order to assess the hemostatic state of patients with bleeding disorders treated by various hemostatic agents or undergoing surgeries. Our studies focus on thrombin, the pivotal factor in the coagulation cascade. Based on ex-vivo thrombin generation (TG) analysis, we are studying the ability of combined treatments, new drugs and innovative non-replacement approaches to induce hemostasis in patients’ plasma. By exploring the coagulation cascade, we aim to predict the hemostatic state of patients, and to tailor personal therapies for patients with bleeding disorders. These studies also enable avoidance of hypercoagulability and potential thrombotic complications.

The coagulation system involvement in ocular pathologies. We explore the impact and significance of hemostatic pathways in the eye. We are focusing on ocular pathologies involving bleeding, impairment of blood retina barriers and growth of pathological blood vessels. Using cell cultures, an animal-based

Early and late fluorescein angiograph images of an eye with 3 laser spots treated with saline (I, II) or APC (IV, V) and images of histological sections labeled with FITC-dextran (green) and DAPI (blue) in saline (III) and APC (VI) treated eyes. Arrow indicates the laser spot area.
models and human samples we are trying to find a new therapeutic approach for ocular pathologies. Recently we found that the coagulation inhibitor Activated Protein C (APC) significantly inhibited choroidal neovascularization (CNV). Formation of CNV is a hallmark of age-related macular degeneration and a leading cause for blindness and our long-term goal is to develop a novel treatment for CNV.

Investigating Autoimmune Diseases: Progress Towards Personalized Medicine

Position
Senior Lecturer, Faculty of Medicine

Research
Our Laboratory focuses on autoimmune pathologies and especially in Systemic Sclerosis (Scleroderma), a connective-tissue disease characterized by vascular alterations and severe fibrosis. The Lab operates a biobank of more than 1100 sera and blood cells collected from rheumatic patients.

Research is conducted in several areas with the aim of promoting personalized medicine:

1) Discovering markers (such as young cells, autoantibodies and miRNAs) for evaluation, diagnosis and prediction of autoimmune diseases and their complications.

2) Understanding mechanisms underlying disease progression

3) Exploring the effectivity and mechanism of action of new treatments for autoimmune diseases.

Our laboratory work combines techniques of cellular and molecular biology. The studies are based on close collaborations between researchers and physicians, which promote access to human tissues and to up-to-date clinical approaches and novel strategies. The strength of the laboratory is its ability to combine in vitro experiments with primary cell cultures and the patients’ blood samples with the patients’ clinical / Laboratory data, to have a deeper understanding of the biological mechanisms involved in the different clinical complications.

We study Influenza, RSV, Adeno, hMPV, Parainfluenza, and Corona viruses, including MERS and the new corona virus nCoV 2019. Our laboratory is part of the World Health Organization (WHO) National Influenza Center (NICs) global network. As a national center, our lab is involved both in routine diagnostic and epidemiological work and in research and development, focusing on pathogenesis and epidemiology of respiratory viruses, and on development and evaluation of laboratory assays, vaccines and antiviral drugs. We investigate several respiratory viruses in particular. These include: Influenza (including the pandemic influenza virus H1N1pdm), HMPV, MERS, SARS, nCoV 2019 and RSV.

Molecular Epidemiology of Human Viruses with Focus on HIV and Viral Hepatitis

Positions
Senior Scientist, Epidemiology and Preventive Medicine Faculty of Medicine, Faculty of Medicine
Director, National HIV and Viral Hepatitis Reference Laboratory; Head, Clinical Virology Laboratory, Central Virology Laboratory, Israel Ministry of Health, Tel Hashomer

Research
We study the molecular and clinical epidemiology of human viruses with focus on blood borne viruses including HIV, hepatitis A virus (HAV), hepatitis B virus (HBV), hepatitis C virus (HCV), hepatitis delta virus (HDV), hepatitis E virus (HEV) and also parvovirus B19 (B19). Recently we are also studying human papilloma viruses (HPV) especially at target populations such as men having sex with men (MSM) who are either HIV positive or negative. We focus of developing and implementation of new molecular or serological based tools for diagnosis of human viruses. We monitor the circulation and presence of HAV and HEV in Israel. We establish non-invasive biomarkers for monitoring of disease progression especially for HBV and HDV, regularly perform molecular resistance analysis of HIV, HCV and HBV patients following treatment failure, and maintain a national data base our all results, enabling in-depth epidemiological research.

Mechanisms of Stress Vulnerability to Develop Post-Stroke Cognitive and Affective Deterioration

**Positions**
Senior Lecturer, Faculty of Medicine
Head of research group and lab: Focus on Stroke and Vascular Dementia, TASMC

**Research**
We study neuro-psychiatric complications after stroke. Stroke survivors are at high risk of developing a wide range of psychiatric symptoms: depression, anxiety, dementia and stress-related symptoms, which contribute significantly to poor recovery.

We conduct both translational and interventional clinical studies, in search for prodromal biomarkers for vulnerability to develop post-stroke dementia and affective deterioration, as well as novel therapeutic options.

In the last two years, we have founded a pioneer proof-of-concept trial funded by the Alzheimer’s Association and the Gates Foundation. In this multi-center (five stroke centers in Israel) Phase-II trial we are investigating the potential of the licensed drug Maraviroc, a CCR5-antagonist, in preventing progression to vascular dementia. This interventional study is based on genetic and clinical results from our previous longitudinal TABASCO study. We investigate the hypothesis that blocking CCR5 modulate signaling cascades implicated in memory and in depression.

Recently, we have initiated another two interventional studies investigating Maraviroc in post-stroke depression and in major depression, as well as experimental model for blocking CCR5 in depression.

Task force member, Task Force on Global Guidelines for Falls in Older Adults

Research
At the Center for the Study of Movement, Cognition, and Mobility, we investigate balance, walking, and falls as well as the prevention and restoration of loss of mobility, motor function, and cognition associated with aging and neurological disease (e.g., Parkinson’s, multiple sclerosis, Alzheimer’s, post-stroke, children with ADHD). Our research team leverages a combination of clinical, engineering and neuroscience expertise to achieve three main objectives: 1) acquire new understandings of the mechanisms that contribute to cognitive and motor function and their changes with aging and disease; 2) construct and validate new methods and tools for early detection and tracking of cognitive and motor decline associated with aging and neuro-degeneration. This

Examples of the modalities that we use to study, assess and treat gait, balance, falls and motor-cognitive interactions.

Investigating Gait, Balance, Falls and Motor-Cognitive Interactions in Aging and Disease

Mechanisms Assessment Treatment
includes the development of new “bio-markers” that can be used for early diagnosis, prognosis, and for quantitative tracking of disease progression, aging, and the response to therapeutic interventions (e.g., at-home monitoring using wearable devices and machine learning) and 3) develop novel methods for prevention and treatment (e.g., using virtual reality, pharmacologic therapy, motor learning, non-invasive brain stimulation).

Examples of ongoing projects in the lab include a) fMRI, EEG, and fNIRS imaging of balance and gait in Parkinson’s disease and aging during usual walking and during challenging conditions such as when negotiating obstacles; b) virtual-reality based intervention for gait and cognitive function in older adults and patients with multiple sclerosis; c) transcranial direct current stimulation to study the mechanisms and to ameliorate freezing of gait in patients with Parkinson’s disease; d) Smartphone-based intervention to improve gait and cognition and to reduce fall risk in older adults; e) transcranial direct current stimulation to study the mechanisms and to reduce fall risk and the effects of dual tasking in older adults; f) investigation of genetic contributions to gait and mobility; g) 24/7 monitoring of gait and mobility using body-fixed sensors to study the effects of osteoarthritis on mobility and to identify early markers of Parkinson’s disease. h) neural network studies of cognitive aging and mobility; i) effects of high intensity exercise on cognition, gait and mobility in older adults with mild cognitive impairment.

Research
We focus on a multi-modal investigation of the human cognitive experience, using functional and structural brain imaging, behavioral rating and physiological measures. The main line of research is investigation of levels of information processing in healthy older adults and participants with amnestic mild cognitive impairment (a-MCI). In particular, we study the neuroprotective role of physical exercise and its physiological adaptations in older population and in individuals with a-MCI.

Publications

Inter-subject correlations of responses across participants from the aerobic group that listened to the narrated story. After 4 months of aerobic training program, participants demonstrated reliable responses (high inter-SC) to story in the parietal (e.g. temporo-parietal junction) and frontal (e.g. inferior frontal gyrus) areas. Moreover, this pattern was close to those shown by healthy older adults.

Functional Neuroimaging Laboratory

Positions
Head, Functional Neuroimaging Laboratory, Department of Diagnostic Imaging, Sheba Medical Center, affiliated to Faculty of Medicine

Research
The functional neuroimaging lab focuses on the diagnosis and prognosis of brain pathologies, in particular the way the brain reorganizes due to acute and chronic neuro-pathologies and how such reorganization in both brain structure and function corresponds with cognitive outcome.

Our research applies multimodal neuroimaging acquisition and analytical techniques (structural, functional and connectivity) together with demographic, clinical, cognitive and genetic data aimed to identify disrupted brain networks and to improve prediction of prognosis in clinical populations such as traumatic brain injury, dementia, type-2 diabetes, and depression.

The objective of our research is to translate into clinical practice. Our translational research aims to improve the diagnosis and prediction of brain pathology’s progression, to plan medical and rehabilitative interventions for the well-being of patients with neuropathologies.

Our lab also provides support for all stages of presurgical clinical fMRI assessment, including paradigm building, fMRI scanning and data analysis. Presurgical clinical fMRI is used for functional mapping in patients with epilepsy and brain tumors in order to localize brain function.

Publications

The relation between severity of TBI and working-memory brain activation during an n-back task. Maximum intensity projections in three orthogonal views of the brain (from left to right: sagittal, coronal and axial) depict areas of significant activation (p<0.005, k>100) in a one-tailed-t statistic contrasting MR signal increases. The color scale shows t-values to the right. a, c: 2->0-back= high WM load; b, d: 2->1-back= WM load increase; CTRL= controls; mTBI= mild TBI; msTBI= moderate-severe TBI. mTBI patients further activated bilateral prefrontal and left parietal regions. msTBI patients revealed greater activation than controls in frontal, parietal and limbic regions.

Investigating the Underlying Neural Mechanisms that Contribute to Changes in Function

**Positions**
Lecturer, Faculty of Medicine

**Research**
We aim to investigate, identify, and quantify the underlying neural mechanisms that contribute to changes in mobility among older adults, people with Parkinson’s disease (PD), and others with neurodegenerative disease. We focus on developing and applying several complementary neuroimaging methods as EEG and fNIRS to evaluate the compensatory brain mechanisms that are activated to enable mobility and function in the presence of aging and neurodegeneration. Our goals are to better understand the role of the CNS in every-day life function, to identify biomarkers reflecting disease, and to evaluate the utility of these biomarkers in identifying individuals with a high risk of developing neurodegenerative disease. Our research has important impacts on personalized medicine as it promises to describe the person's abilities and the compensatory mechanisms utilized on an individual level. This in turn could enable the tailoring of specific gait interventions, providing personalized medicine approaches to the benefit of the individual patient and the healthcare system.

Investigating Early Markers of Neurodegeneration

Positions
Associate Professor, Neurological Department, School of Medicine
Faculty Member, Sagol School of Neuroscience
Director, Laboratory for Early Markers of Neurodegeneration, Tel Aviv Sourasky Medical Center

Research
Research in the LEMON lab is performed in a clinical setting. Our mission is to identify new markers of ageing and neurodegeneration. More specifically, we aim to better understand the pathological process of neurodegeneration and its progression. We investigate clinical, biological and neuronal markers using different tools such as neural-imaging (e.g., MRI, fMRI, EEG and fNIRS) and body fixed sensors with the overall aim of identifying sensitive measures that can quantify progression and predict neurodegeneration in prodromal and healthy individuals and populations at risk due to genetic mutations. In addition, we are exploring measures of successful ageing, ways to better understand the interplay between motor and cognition functions, methods to evaluate reserve capacity in health and disease and potential behavioral modifications that have the potential to increase the likelihood for successful ageing.

Publications

Subtle changes in acceleration as collected by wearable sensors. The signals show different patterns of movement in a person with early stage Parkinson’s disease and a healthy subject at risk for developing Parkinson’s disease as compared to healthy age matched controls. Features such as these are explored in the context of additional measures (imaging and biological) to construct a cumulative predictive model of disease, disease progression and ageing.

Investigating the Biological Basis of Severe Mental Illness

Positions
Head, Pediatric Molecular Psychiatry Lab, Sheba Medical Center, Faculty of Medicine
Senior Lecturer, Faculty of Medicine

Research
Our laboratory, situated within the Sheba Medical Center, operates under the leadership of Prof. Doron Gothelf as part of the Division of Child and Adolescent Psychiatry. Our primary focus is utilizing molecular and genetic methodologies to enhance our understanding of the biological underpinnings associated with various psychiatric disorders and general pathological aspects of mental illness.

Specifically, our research delves into investigating the intricate relationship between the immune system, blood–brain barrier (BBB) permeability, oxidative stress (OS), and the brain in pathological conditions. There is growing evidence that neuroinflammatory factors are involved in the pathophysiologic mechanisms leading to schizophrenia, along with genetic components. We study the 22q11.2 deletion syndrome (22q11.2DS). Individuals with this syndrome have a microdeletion of a section of the long arm of chromosome 22 and have a characteristic phenotype including immunological abnormalities and other pathologies. Individuals with 22q11.2DS have a 30% risk of developing schizophrenia. As a result, this syndrome is an optimal genetic model for studying the interaction between the immune system and schizophrenia.

Our lab is located at the heart of the intersection between basic science and clinical practice.

Extreme Childhood Irritability (ECI), characterized by agitation and violent outbursts, is one of the most prevalent reasons for children being referred to psychiatric care. It manifests across multiple childhood psychiatric disorders. In our laboratory, we assess various aspects of the immune system, BBB permeability, OS, as well as the glutamate and GABA ratio in young children.

Our laboratory enjoys a prime position, as it’s strategically located at the intersection of basic science research and clinical practice. Our affiliation with the Division of Child and Adolescent Psychiatry means that all our investigations revolve around human tissues, predominantly blood samples, accompanied by meticulous clinical observations. Our team consists of experienced clinical researchers and senior neuroscientists who work collaboratively, fostering a multidisciplinary approach to our research endeavors.

The Neuronal Encoding of Human Speech

Positions
Senior Lecturer, Faculty of Medicine and Sagol School of Neuroscience
Senior Researcher and Neurophysiologist, Functional Neurosurgery Unit, Tel Aviv Sourasky Medical Center ("Ichilov")

Research
The goal of our research is to understand how speech is represented in the human brain at the single neuron level in health and neurological disorders. We take advantage of a unique clinical "opportunity" to work with neurosurgical patients undergoing implantation of electrodes for clinical reasons. Experiments are conducted intraoperatively with awake patients with movement disorders or in the ward, with epilepsy patients. We investigate multiple levels of speech constructs, for example the acoustic, phonetic and phonological levels, during the production, perception and imagery of speech. We focus on three aims:

1. Understanding the encoding of speech features by single neurons (see Figure 1 for an example).
2. Exploring the degradation in the neuronal representation of speech due to neurological disorders, for example in Parkinson’s disease.
3. Developing brain-machine interfaces for restoring speech faculties in completely paralyzed persons.

![Image of neuronal encoding](image-url)

Medial-frontal units that we have discovered, with high specificity to vowels. Raster plots and peri-stimulus time histograms of five units (rows) during the articulation of the five vowels a, e, i, u and o (columns). The response of each unit is specific to one or two vowels only. Red vertical dashed lines indicate speech onset. All vertical scale bars correspond to firing rates of 20 spikes/s (from: Tankus et al., Nature Communications, 2012).
by decoding their neuronal activity (i.e., inferring speech contents solely from neuronal activity).

Our research is a first step towards therapeutic intervention to alleviate speech disorders in Parkinson's disease and avoid speech-related side effects of deep brain stimulation. Our studies therefore bear enormous potential to greatly improve the quality of life of millions of people around the globe.

Human Milk Research

Position
Senior Researcher

Research

The ongoing research at our department focuses on Human Milk (HM) and lactation. HM is dynamic and provides macronutrients (fats, carbohydrates and proteins), micronutrients (vitamins and minerals) and non-nutritive bioactive factors (Human milk oligosaccharides, immunoglobulins, cells, growth factors, etc.) that promote survival and healthy development of the infant. Our laboratory is equipped with a Human Milk Analyzer from MIRIS.

We study the influence of various environmental, maternal and neonatal variables upon HM macronutrient composition. These include collection and storage conditions of HM, nasogastric-tube-feeding, seasonal variation, fenugreek diet supplementation, pre-pregnancy BMI, gestational diabetes mellitus, maternal anxiety, physical activity and age, between-breast differences, length of lactation, the practice of tandem-breastfeeding (two or more offspring of different ages who are breastfed by their mother at the same time), infant’s gender, status of Small for Gestational Age versus Appropriate for Gestational Age of preterm infants, and singleton versus twin pregnancies effects. We also look into the use of aluminum-based antiperspirants on HM aluminum content, the HM content of Covid-19-specific antibodies following Covid-19 vaccination during pregnancy or following maternal Covid-19 infection and the correlation between levels of lutein in HM and the occurrence and severity of retinopathy of prematurity (ROP) in preterm infants.

Biological Monitoring Using Micro and Nano-Sized Particles Distribution Measurement in Biological Samples to Early Detect Health Impairment in Environmental and Occupational Lung Settings

Positions
Head, Laboratory Pulmonary and Allergic Diseases
Chair Department of Environmental and Occupational Health, Tel Aviv University

Research
The "ultrafine hypothesis" suggests that smaller particles are more potent than larger particles at driving inflammation; leading to the initial proposal that respiratory ill health was associated with the number of ambient ultrafine particles. When first introduced in 1994, the "ultrafine hypothesis" met friendly skepticism, with opponents arguing that NSP (nano-sized particles) are very short-lived and disappear through heterogeneous and homogeneous aggregation within seconds or minutes and therefore are toxicologically irrelevant. This skeptical attitude has changed considerably. Research teams across the world are now working now on NSP, and there are multidisciplinary alliances among atmospheric scientists, epidemiologists, clinicians, and toxicologists, among others. Nonetheless, substantial research gaps continue to prevail. Most of the initial assessments of particulate burden and involvement of inflammatory and structural cells in occupational lung diseases were made in studies using fibreoptic bronchoscopy in conjunction with bronchoalveolar lavage (BAL). The relative invasiveness of this technique, however, has restricted the use of bronchoscopy to a limited

Biological monitoring by measurement of micro range particles in induced sputum samples

Figure 1
number of specialised centres, and hampered its development into a practical and suitable tool for screening programmes, exposure evaluation or repeated follow-up of workers exposed to hazardous dust in large populations.

The ongoing search for non-invasive techniques has led to a number of development approaches, such as the examination of cells, quantification of biochemical mediators, and characterization of particulate matter in samples of induced sputum (IS) as well as the quantification of biochemical mediators and characterization of particulate matter in the condensation of exhaled breath condensate (EBC).

In the last years, we have concentrated our research on the application of these techniques in occupational and environmental exposures:

- **Particle size distribution (PSD) and dynamic shape characterization (DSC):** The size and shape of the particles will be assessed from the rich cell fraction of the processed plugs with the Eyetech Analyzer and the analyzer’s video channel (Donner Technologies, Israel) using a PSD method in the range of 0.5-3,600 based on the time of transition theory where the duration of interaction between beam and particle provides a direct measurement of each particle’s size (Fig 1).

- **NSP measurement.** The size and shape of the ultrafine particles (PM$_{0.1}$) are assessed from the rich cell fraction of the processed plugs in the IS sample and the EBC sample, with the NanoSight LM20 using the Nanoparticle Tracking Analysis (NTA) method of visualizing and analyzing particles in liquids that relates the rate of Brownian motion to particle size. The rate of movement is related only to the viscosity of the liquid, the temperature and the size of the particle and is not influenced by particle density or refractive index (Fig 2).

We studied several populations: Workers exposed to hazardous dust at the Israel World Trade Center (WTC), dust-exposed firefighters in the USA ten months after the WTC disaster, dental technicians exposed to beryllium (funded by the Binational Science Foundation BSF 2007-2011), workers exposed to artificial stone dust and asthmatic children in the Tel Aviv area. Our ongoing research is on the field that characterize the mineral compositions of these particles and their biological effect.

Genetic and Epigenetic Regulation of Spermatogenesis for Personalized Diagnosis and Treatment of Male Infertility

Position
Senior Lecturer, Faculty of Medicine

Research
Our lab works towards uncovering the etiology of male infertility. Our goal is to better understand the spermatogenetic process and improve the diagnosis and the treatment of men with infertility and subfertility. We are applying genetic approaches, combined with endocrinology, histological and cytological approaches in human specimens and mice models. By focusing on the Israeli Jewish and Arab population, our study has identified three new genes, each one playing a pivotal role in different critical processes occurring during spermatogenesis. We are employing deep sequencing to identify additional new genes mutated in infertility and subfertility. Batteries of genes are exclusively expressed at specific stages during spermatogenesis. By studying meiosis, gene expression and gene regulation, we identified testicular molecular markers that predict the presence of sperm in the testis. At present, we are working on detecting markers in semen that can predict testicular sperm cells by studying the seminal small RNA transcriptome and genetic and epigenetic regulation of spermatogenesis for personalized diagnosis and treatment of male infertility.

Expression pattern of PATE protein during spermatogenesis. Immunofluorescence analysis reveals the cell stages and the location in which the PATE protein is detected.

hESCs in Development, Genetic Disorders and Cell Therapy

Positions
Director, IVF Lab and Wolfe PGD-Stem Cell Lab, Tel Aviv Sourasky Medical Center
Professor, Department of Cell and Developmental Biology, Faculty of Medicine

Research
The Wolfe PGD-Stem Cell Lab focuses on studying issues related to early embryonic and developmental processes, genetic disorders and different aspects of cell therapy using our unique collection of PGD-derived human embryonic stem cells (hESCs).

We derive hESCs directly from affected embryos, which are obtained as a by-product of the preimplantation genetic diagnosis (PGD) procedure. PGD is performed for couples at high risk of transmitting a genetic defect and who wish to ensure the birth of a healthy child. It requires in vitro fertilization (IVF), which makes the preimplantation embryos available for biopsy and single-cell molecular analysis. Following IVF-PGD, embryos diagnosed as being disease-free are transferred into the uterus for implantation, whereas the affected embryos that would be otherwise discarded are used to establish hESC lines that carry the naturally inherited mutations. This setup provides the benefit of efficient coordination between the generously donated affected embryos and the stem cell lab that focuses on researching these very unique samples. By means of these capabilities, we have already established >50 mutant hESC lines associated with 18 different inherited disorders.

These lines make it possible for us to study the molecular and pathophysiological mechanisms underlying the genetic disease of which they were diagnosed. In addition, since we have a large collection of hESC lines derived under the same conditions, we are able to perform different studies on the pluripotent, genetic and epigenetic properties of these cells.
